cWR-package (cWR) R Documentation

Composite endpoint analysis for time-to-event data using Win Ratio

Description

This package uses Win Ratio (WR) as a summary statistic to compare the composite endpoints of time-to-event data between two groups. Options of clustered or independent time-to-event data can be specified

```
cWR(treatment, cluster,
     y1, y2,
delta1, delta2,
null.WR=1, alpha.sig=0.05)
```

treatment. An integer vector with code 0 as control group and 1 as treatment group for each subject

An integer vector with unique cluster ID for each cluster. When subjects are independent, the cluster ID is unique for each subject. cluster

Let T_H, T_D and T_C be time to non-fatal event, time to fatal event and censoring time, respectively. y1 is a numeric vector with min(T_H, T_D, T_C) for each subject.

A numeric vector with min(T_D, T_C) for each subject

An integer vector with code 1 indicating that T_H is observed, 0 otherwise delta1 delta2 An integer vector with code 1 indicating that T D is observed, 0 otherwise null.WR The null hypothesis of the WR statistic. The default is H0: WR=1 or log(WR)=0

alpha.sig The significance level, with default value 0.05

Details

y2

The function "cWR" performs significance testing of comparing two composite time-to-event outcomes between groups. The Win Ratio summary statistic is built on the "unmatched" approach described by Pocock et al. (2011). We assume that the composite endpoints can be formulated as semi-competing risk data. Each individual in the study is measured on time to non-fatal (non-terminal) event (e.g. hospitalization) and time to fatal (terminal) event (e.g. death). Specifically, the fatal event is considered clinically more important compared to the non-fatal event. Censoring is allowed, but time to censor needs to be observed.

This function can handle independent data, as well as clustered data. The inference of clustered data is based on the generalized bivariate clustered U-statistics proposed by Zhang and Jeong (2019). This clustered U-statistic accounts for the potential correlations among subjects within a cluster. When the cluster size is 1, it's the independent setting and the inference is the same as the method proposed by Bebu and Lachin (2015).

Note: The option "treatment", "cluster", "y1", "y2", "delta1", "delta2" are required and no defaults are provided. These options have to be vectors with the same length. No missing values are all

```
First estimated clustered U-statistic
          Second estimated clustered U-statistic
logWR Estimated WR on log scale
         Estimated standard error of the WR on log scale
          Test statistic
          100(1-alpha.sig)% confidence interva
          P-value of the significance testing
var_cov Variance and covariance matrix of the first and second clustered U-statistics
```
